An electrical fault detection apparatus comprises a detector (3), a threshold detector (4), duration discriminator (5) and warning device (6). Electrical signals radiated due to a fault having a certain frequency, above a certain amplitude and of a certain duration are detected and employed to activate a warning device (6) to indicate a fault condition in an electrical cable likely to lead to a fire.

APPARATUS AND METHOD FOR DETECTING A POTENTIALLY  
FIRE GENERATING ELECTRICAL FAULT

5 The present invention relates to apparatus and  
method for detecting a potentially fire generating  
electrical fault.

10 The fire risk of electrical faults in electrical  
supply systems particularly, but not exclusively in  
buildings, is well known.

An object of the present invention is to provide  
means to detect electrical faults which are likely to  
cause a fire risk, at an early stage before a fire is  
15 likely to occur. The current method of preventing  
electrical fires is to provide an overload isolation  
device such as a fuse or an overload circuit breaker.  
These devices isolate excessive currents flowing from  
short circuits after a very short time. In this way,  
20 the joulean heating in cables is limited and hence the  
cables do not set on fire. However, a second form of  
fire hazard has been recently investigated and it is  
believed that a large number of domestic and indeed  
industrial fires start in this way. This hazard arises  
25 from an intermittent break in a cable, by either damage,  
excessive flexing in operation or incorrect  
connection and termination. Neither fuses nor circuit

-2-

breakers respond to this type of fault. The present invention relates to apparatus for and a method of dealing with the potential hazard.

5           If there is a break in continuity in either the live or neutral of a mains supply to a load, then any vibration will cause the circuit to momentarily switch on and off at the break with a resulting arc. The arc can be especially severe in the presence of a  
10          non-deionised water, and it has been demonstrated that such an arc can in a worst case create a fire within about 8 seconds given the appropriate circumstances where there is a fracture in either the live or neutral wire of a flexible cable supplying an object such as a  
15          washing machine. Under these circumstances, the electrical load of the appliance limits the current flow, neither fuses nor earth leakage circuit breakers offer any protection. Indeed, the machine continues to function albeit spasmodically whilst a fire is started.

20

          Experiments have shown that arcs arising from breaks and bad connection generate significant energy in the radio frequency spectrum. In the frequency range of a few hundred KHz, the energy is particularly strong and  
25          indeed propagates with minimal attention over the whole mains cable network certainly to cover wiring within a domestic house or small industrial premises. Following the first such arcing, there is often damage to nearby

-3-

insulation resulting in the formation of carbon tracks.

Further the copper conductors work harden and further flexing exacerbates the break. If the break is in the open state, the appliance will of course not function.

5       Nonetheless, small currents of a few milliamps flow along the carbon tracks and such currents also generate r.f. signals but at a significantly low level than that generated by the arc itself.

10           Commutator motors generate arcs in normal use and the r.f. generated by such machines are of the same size as that generated from a dry break in a mains cable. However, for a number of years the BS800 specification has been applied and conforming appliances  
15       have to contain suppression filters to limit the energy of r.f. propagated especially in the region of 160KHz. Measurements have shown that arcs in faulty cables generate a signal similar to unsuppressed commutator motors such as hand drills. However, BS800 suppressed  
20       hand drills generate r.f. at least an order of magnitude less. Suppressed thyristor devices, such as dimmer switches, produce even lower levels of r.f. It is concluded, therefore, that in a normal environment, arcs generated from faulty cabling can be detected by using  
25       devices to measure the r.f. energy present on the mains network within the premises. The level of this energy is sufficiently different to enable discrimination to be achieved over the above normal domestic and light

-4-

industrial and commercial appliances operating within the BS800 specification.

According to one aspect of the present

5 invention there is provided apparatus for detecting an electrical fault in an electrical supply system, characterised by means for detecting an electrical signal radiated within a given band of the radio frequency spectrum, means for determining if the

10 amplitude of that signal exceeds a certain threshold, means for determining if the duration of the signal exceeds a certain value and means for indicating when such a signal above the threshold amplitude and above the duration value has been detected whereby to

15 indicate fault conditions.

According to another aspect of the present

invention, there is provided a method of detecting an

20 electrical fault in an electrical supply system, characterised by the steps of detecting an electrical signal radiating within a given band of the radio frequency spectrum determining if the amplitude of that signal exceeds a certain threshold, determining if the duration of that signal exceeds a certain value, and

25 indicating if such a signal above the threshold and above the duration value has been detected whereby to indicate fault conditions.

-5-

In order that the invention may be more clearly understood embodiments of the invention will now be described, by way of example with reference to the accompanying drawings, in which:-

5

Figure 1 shows a block circuit diagram of a first form of detection apparatus according to the invention,

10

Figure 2 shows a block circuit diagram of a second form of detection apparatus according to the invention, and

15

Figure 3 is a detailed circuit diagram of the main parts of the embodiment of Figure 1.

20

Figure 1 shows part of a mains network 1 to which is attached an interface unit 2, the purpose of which is to provide a low impedance path for the r.f. whilst blocking the very much larger 50/60Hz mains signal.

25

It is considered that the best frequency of operation is about 170KHz with a bandwidth of about 10KHz to 20KHz. This range will enable the filter to reject 200KHz signals for radio 4 on long wave and will enable significant attenuation of signals at 150KHz which will be increasingly used by security systems

-6-

operating with mains borne signalling. Unit 3, provides for an r.f. detector, which will operate at the chosen centre frequency and will provide the desired bandwidth.

5           The level of r.f. signal detected is then processed by a threshold detector 4, which provides a warning signal if the r.f. exceeds a predetermined threshold. Signals generated from normal devices will also generate r.f. but these will not exceed the 10 predetermined threshold. Arcing typically generates mains borne noise in the frequency band 160KHz to 180KHz in pulses of minimum duration of 500ms of amplitudes from 10mV to several volts. Background noise in the same frequency band in a typical mains installation 15 under normal operating conditions contains pulses of up to 200ms duration of amplitudes up to 40mV. Shorter pulses in the order of microseconds can have amplitudes up to several kilovolts. BS800, to which all domestic appliances must conform, allows r.f. pulses of 200ms 20 duration or longer up to 6mV amplitude. A minimum amplitude threshold level of 6mV is therefore proposed.

             Arcing occurs when any switch closes or especially opens an active electric circuit. For 25 example when turning off a light a pulse of r.f. of considerable magnitude is generated. However, arcs from faulty connections occurs over a much greater time duration. The warning signal is passed to the duration

-7-

descriminator, 5, the purpose of which is to produce a signal only if the large r.f. signal is present for longer than a predetermined time as indicated above.

5 The r.f. signal may be generated in a stream of closely spaced signals. The duration descriminator typically may be set to deliver a fire risk signal if the r.f. persists for 0.6 or more seconds. The descriminator will contain a predetermined time constant, typically less than one second, such that a pulsed stream of r.f. 10 signals more closely spaced than this predetermined time constant, will be treated as a continuous signal. The object of this descriminator 5, is to prevent alarm signals being generated by bouncing switches in normal appliances.

15

The descriminator generates a latched alarm signal which then can be used to drive some warning device which may be audible and/or visible. The option also exists to use this signal to operate a latched 20 circuit breaker 7, which isolates the circuit.

A typical device may generate the d.c. power source to operate its circuits from either an internal battery or more likely from a power supply unit, 25 13, deriving a low voltage d.c. supply from the mains. In certain situations it may be desirable that an embodiment of the device may be connected to the mains via a switched socket. It is undesirable that such a

-8-

device be inadvertently disconnected by switching the  
socket off. The device should therefore be fitted with  
power-off warning means, 8. The simplest way to  
generate such a warning is to provide a warning light to  
5 indicate active connection to the mains.

As the proposed device is typically passive in a  
normal environment and may remain so for very  
considerable periods of time, it is important to supply  
10 means to test the system. It is proposed that a test  
signal generator, 9, be incorporated to provide an r.f.  
signal of the correct amplitude. This is connected to  
the device by switch 10, which typically would be a test  
button. On pressing, 10 for a period longer than the  
15 predetermined duration in the descriminator 5, then the  
correct action of the device would ensue. The r.f.  
signal generated would also pass through the mains  
interface and would be transmitted via the network to  
any other like devices which were connected. They in  
20 turn would be activated by the test signal and this  
would test the integrity of the entire connection  
through the network. This is important because certain  
loads such as TVs, fluorescent fittings and washing  
machines etc contain capacitors across the mains, with  
25 the result that r.f. signals are strongly attenuated at  
such a load. This problem can be overcome by using a  
number of devices strategically placed. Some devices  
could be built into accessories. For example, a double

-9-

sized socket could contain one single mains outlet together with an associated safety device occupying the adjacent space. To solve the attenuation by fluorescent systems, light fittings could be designed with a safety 5 device incorporated.

As an alternative solution, it is technically possible to modify the capacitative filter in some of these appliances in order that r.f. propagated on the 10 mains network is not significantly attenuated. The application of mains-borne signalling requires this to be done. In certain cases, mains adaptors containing the necessary filter elements must be inserted between the device and the mains socket. Such devices would 15 also permit propagation of r.f. signals due to faulty wiring to be detected by the described invention.

In certain applications, where the devie is required to isolate a zone of the mains network if a 20 fault is detected in the zone, such as 1, in figure 1, by activating the circuit breaker 7. It may be appropriate to include a low pass filter, 11, so as to prevent r.f. generated by faults or during test from affecting the remaining network. Similarly, any r.f. 25 activity on the remaining network will be isolated by the filter 11 and prevent it from triggering a response in the protected network, 1. This is especially important if the device is resident in a consumer unit.

-10-

If two adjacent properties operated such a system without the filter, 11, present, then faults in one, would result in disconnection of both; clearly undesirable. In the same way it will be desirable to 5 fit a low pass filter, 11, in a consumer unit to avoid a fault in an adjacent premises supplied on the same phase of the mains, triggering the warning device. Figure 3 shows a detailed circuit implementation of the embodiment shown in Figure 1. In this implementation, 10 for commercial and practical reasons, the circuit breaker 7 and low pass filter 11 have been omitted. The remaining circuit blocks of Figure 1 are enclosed by a dashed line in Figure 3 and identified by the same reference numerals.

15

By way of example a second embodiment of the device will be described by reference to Figure 2.

Any r.f. signal generated by an arc in a mains 20 circuit not only propagates along the mains network but is radiated as an electromagnetic wave. As the mains network is large and acts as an aerial, the radiation is of a significant magnitude such as to make detection within the premises relatively easy.

25

This can be done in a free standing device acting as an r.f. detector being provided with an aerial, 14, connected to an r.f. detector and filter,

-11-

15. Again it is suggested that 170kHz with a 10 to 20 kHz bandwidth be more appropriate as before described.

5        The signal generated is then passed to a threshold detector, 16 and a duration discriminator, 17 which feeds some warning device 18. These functional blocks perform the same function as blocks 4,5 and 6 respectively in Figure 1, and could be of an identical design.

10

      The free standing device would normally be battery operated although power for its operation could be derived from the mains. In the case of battery operation the device would normally be permanently on 15 and the battery condition would be detected by circuit, 20 and if low would initiate a warning by means of item 21.

20       It may be desirable to operate the device such that any signal indicative of a potentially dangerous fault would trigger latch, 22, which ensures that the warning continues to be activated until the latch is reset by button 23.

25       The advantage of the free standing device is that it is more portable and does not suffer to the same degree as the mains resident device from capacitative attenuation by specific loads. However, it will be more

-12-

difficult to define a clear threshold due to the uncertainty of the coupling between the device aerial and the mains network. It will also be difficult to discriminate between faults in closely adjacent premises  
5 as insertion of filters in the consumer unit will not necessarily eradicate the problem. This is because the free standing unit will be subject to direct radiation through party walls arising from radiation present in the adjacent premises.

10

It will be appreciated that the above embodiments have been described by way of example only and that many variations are possible without departing from the invention.

15

CLAIMS

1. Apparatus for detecting an electrical fault in an electrical supply system, characterised by means for detecting an electrical signal radiated within a given band of the radio frequency spectrum, means for determining if the amplitude of that signal exceeds a certain threshold, means for determining if the duration of the signal exceeds a certain value and means for indicating when such a signal above the threshold amplitude and above the duration value has been detected whereby to indicate fault conditions.
2. Apparatus as claimed in claim 1, which is connected to the electrical system in which the fault to be detected would arise.
3. Apparatus as claimed in claim 1, in which the means for detecting comprises an aerial for receiving signals to be detected.
4. Apparatus as claimed in claim 2, in which means are provided for isolating the part of the system in which faults are to be detected from other parts of the system.
5. Apparatus as claimed in claim 2, in which means are

-14-

provided to prevent significant attenuation of a signal to be detected by elements in or attached to the system having an inherent capacitive characteristic.

5       6. Apparatus as claimed in any preceding claim, in which means are provided for indicating that the apparatus is operational.

10      7. Apparatus as claimed in any preceding claim, in which a signal generator is provided operative to supply a signal to the means for detecting to enable the correct functioning of the apparatus to be checked.

15      8. Apparatus as claimed in any preceding claim in which the means for detecting is set to detect a signal having a frequency of about 170KHz with a bandwidth of about 10 to 20 KHz.

20      9. Apparatus as claimed in any preceding claim, in which the threshold duration value of the signal is more than half a second and preferably one second.

25      10. Apparatus as claimed in any preceding claim, in which the amplitude threshold is at least 6 millivolts.

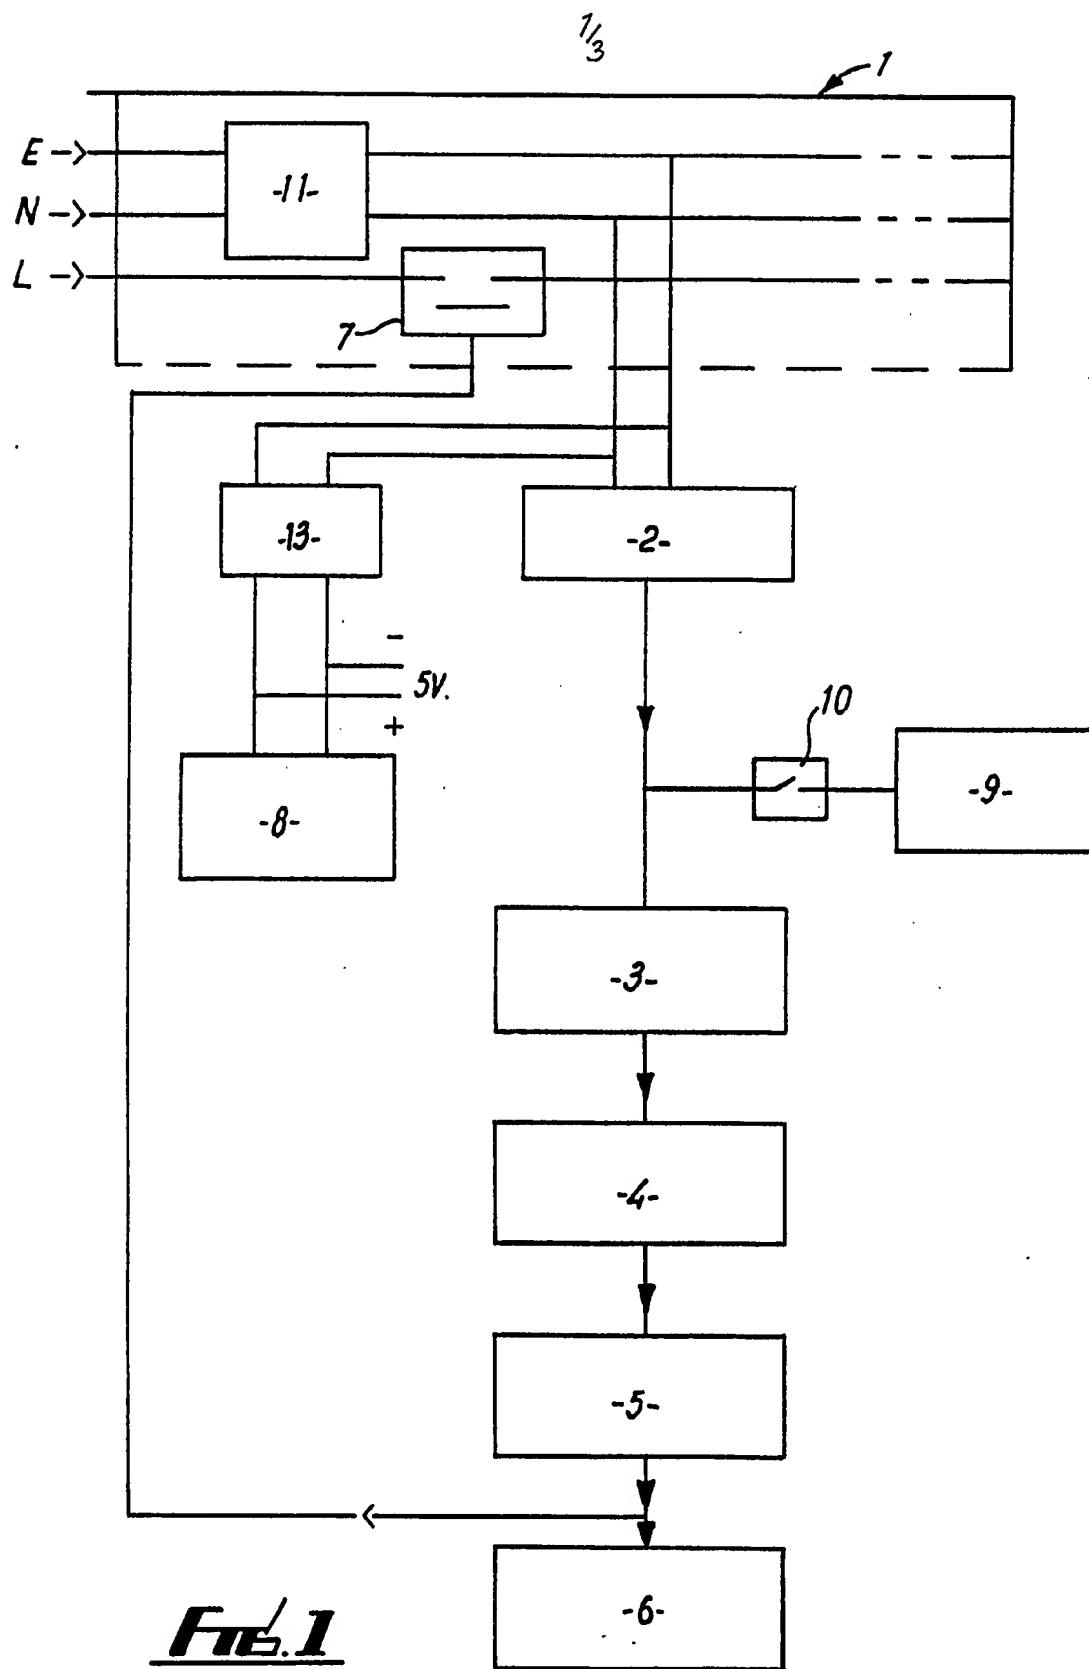

11. A method of detecting an electrical fault in an electrical supply system, characterised by the steps of

-15-

detecting an electrical signal radiating within a given band of the radio frequency spectrum determining if the amplitude of that signal exceeds a certain threshold, determining if the duration of that signal exceeds a 5 certain value, and indicating if such a signal above the threshold and above the duration value has been detected whereby to indicate fault conditions.

12. Apparatus for detecting an electrical fault in an 10 electrical supply system substantially as hereinbefore described with reference to Figures 1 and 3 or to Figure 2 of the accompanying drawings.

13. A method of detecting an electrical fault in an 15 electricall supply system substantially as hereinbefore described with reference to Figures 1 and 3 or to Figure 2 of the accompanying drawings.
